There are two main types of *Staphylococcus aureus* infections. The first is a skin infection, such as a boil or abscess. The second is a more serious infection, such as a pneumonia or sepsis. Both types of infection can be caused by a single bacterium, but the severity of the infection depends on the site of infection and the patient's overall health. In some cases, the infection can spread to other parts of the body, leading to a more serious condition. It is important to seek medical attention if you suspect you have a staphylococcal infection, as early treatment can help prevent complications.
